## Image Formation

## Safety and Equipment

- No special safety equipment is necessary for this lab.
- PASCO Optics Bench
- PASCO Basic Optics Components Kit (OS-8900)

We use these components from the Kit:

- Light Source with power adapter
- Basic Optics Ray Table (round protractor)
- Semicircular D-shaped Lens
- Mirror (inside ray components kit)
- Convex Lenses ( $+100 \mathrm{~mm},+200 \mathrm{~mm},+250 \mathrm{~mm}$ )
- Concave Lens ( -150 mm )
- Viewing Screen

## Introduction

Rays of light are generally straight lines, except when the light is refracted or reflected. Real objects emit light from every point. To make things easier, we usually consider one point at a time, so that the rays we trace are those from a point source called "the Object".

To form an image, the rays from the object reflect or refract and afterward they can be interpreted as passing (or appearing to pass) through a common source point. This common point shared by all of the rays after reflection or refraction is called "the Image".

Individual rays obey the reflection equation or Snell's Law:

$$
\theta_{1}=\theta_{1}^{\prime} \quad n_{1} \sin \theta_{1}=n_{2} \sin \theta_{2}
$$

where $\theta_{1}$ is the angle of an incident (incoming) ray, $\theta_{1}^{\prime}$ is the angle of a reflected ray, and $\theta_{2}$ is the angle of a refracted ray. When dealing with reflection and refraction, angles are measured from the normal.

Figure 1. Refraction Geometry. Note the refracted angle could actually be larger than the incident angle, depending on the indices of refraction.

Images and objects obey the thin lens equations:

$$
\frac{1}{d_{o}}+\frac{1}{d_{i}}=\frac{1}{f} \quad \frac{h_{o}}{h_{i}}=M=-\frac{d_{o}}{d_{i}}
$$

where $d_{o}$ (sometimes called $p$ ) is the object distance and $d_{i}$ (sometimes called $q$ ) is the image distance. When dealing with lenses and mirrors, distances are measured from the lens or mirror. Negative distances are allowed and mean the image is on the "wrong side" of the lens or mirror. Instead of being where the rays are after the lens or mirror, the image is on the other side and the image is virtual.

## Objectives:

- To observe the rays formed from a flat mirror.
- To observe rays refracting from a prism.
- To verify the thin-lens equation.

## Part \#1. Ray Reflection

1. Place the PASCO Light Source directly on the lab table, with the ray table just in front of it. Select the single beam of light, and align the ray table's Normal line with the ray. Place the flat mirror along the Component line of the ray table. The alignment is correct if the reflected ray is on top of the incident ray.

Figure 2. Reflection alignment with ray table and mirror.
2. Rotate the ray table in $10^{\circ}$ increments to control the incident angle. Measure each reflected angle, calculate the \% Error, and comment on the results in the caption.

Table 1. Reflection experiment data. (Comment on results.)

| Incident angle $\theta_{1}\left({ }^{\circ}\right)$ | Reflected angle $\theta_{1}^{\prime}\left({ }^{\circ}\right)$ | \% Error |
| :---: | :---: | :---: |
| 10 |  |  |
| 20 |  |  |
| 30 |  |  |
| 40 |  |  |
| 50 |  |  |
| 60 |  |  |
| 70 |  |  |
| 80 |  |  |

## Part \#2. Ray Refraction

1. Replace the mirror with the semicircular D-shaped Lens. Align the lens with the outline that is drawn on the Ray Table. If the alignment is correct, the beam should exit along the $0^{\circ}$ mark on the other side.

Figure 3. Alignment setup for the refraction experiment, using the D-shaped lens.
2. Turn the Ray Table to control the incident angle in $10^{\circ}$ increments. Observe the ray exiting the lens. Notice that the ray exits perpendicular to the round surface, so that the light is not refracted at the round surface, only at the flat surface. Measure the angle of refraction, which is the direction of the beam inside the lens. Record this in Table 2 Refraction Data.

Table 2. Refraction Data.

| incident angle $\theta_{1}\left({ }^{\circ}\right)$ | Refracted angle $\theta_{2}\left({ }^{\circ}\right)$ | $\sin \theta_{1}$ | $\sin \theta_{2}$ |
| :---: | :--- | :--- | :---: |
| 10 |  |  |  |
| 20 |  |  |  |
| 30 |  |  |  |
| 40 |  |  |  |
| 50 |  |  |  |
| 60 |  |  |  |
| 70 |  |  |  |
| 80 |  |  |  |

3. Calculate the sine of each incident and refracted angle. (Reminder: In Excel, to take the sine of cell A3 measured in degrees, use $=\sin ($ radians $(A 3))$.)
4. Make a plot of $\sin \theta_{2}$ vs. $\sin \theta_{1}$. The slope of this plot is $\frac{\sin \theta_{2}}{\sin \theta_{1}}=\frac{n_{1}}{n_{2}}$. Assuming $n_{1}=1$, use the slope of the plot to calculate $n_{2}$. Include this information in Table 4 Analysis of Results of Refraction Experiment. Comment on the results in the caption.
5. Turn the Ray Table around so that the light is entering the round side of the lens. In this configuration, there are two beams that exit. One is the ray reflected from the flat side of the lens, and the other is the ray refracting from the lens into air.

Figure 4. Setup for measuring refraction from the lens into air. Note that the beam enters the lens at the curved surface and does not bend there. Bending occurs only at the lens-to-air interface at the center of the Ray Table.
6. Control the incident angle in $10^{\circ}$ increments. Measure each refracted angle, calculate the sines in Table 3, and Plot with a trendline. (You may not get data past $40^{\circ}$. Just don't include those points.) This time, $n_{2}=1$ and you should calculate $n_{1}$ from the data. Include the analysis in Table 4.

Table 3. Refraction Data for lens-to-air.

| incident angle $\theta_{1}\left({ }^{\circ}\right)$ | Refracted angle $\theta_{2}\left({ }^{\circ}\right)$ | $\sin \theta_{1}$ | $\sin \theta_{2}$ |
| :---: | :---: | :---: | :---: |
| 10 |  |  |  |
| 20 |  |  |  |
| 30 |  |  |  |
| 40 |  |  |  |

Table 4. Analysis of results of refraction experiments. (Comment on agreement.)

| Experiment | Slope of graph <br> $\left(\sin \theta_{2} / \sin \theta_{1}\right)$ | Known index | Unknown index | Value of Unknown |
| :--- | :---: | :---: | :---: | :---: |
| Air-to-Lens |  | $n_{1}=1$ | $n_{2}$ |  |
| Lens-to-Air |  | $n_{2}=1$ | $n_{1}$ |  |

## Part \#3. Image Formation through Curved Lenses

Case 1: Object Very Far from Lens

1. Place the +100 mm lens on the optics track, perhaps at the 100 cm mark.
2. Place the observing screen on the optics track, about 10 cm from the lens.
3. "Point" the other end of the optics track at a bright, far-away object, such as the window.
4. Move the observing screen to focus the image.
5. Compare the lens-image distance to the focal length printed on the lens.

Table 5. Image formed of a very-far Object. (Comment on agreement.)

| Image Distance $(\mathrm{cm}):$ |  |
| :--- | :--- |
| Focal Length $(\mathrm{cm}):$ |  |
| \% Difference |  |

Case 2: Real images from a convex lens
6. Attach the PASCO Light Source to the optics track at the 0 cm mark. It should easily snap onto the top of the track. Later, to remove the Light Source, there is a little release lever that must be pressed.
7. Place the +250 mm lens on the optics track at the 75 cm mark.
8. Place the observing screen on the optics track, and move it around to obtain a focused image on the screen. (Hint: The screen should be near the 110 cm mark.) Record the object-lens distance and the image-lens distance. (Both are positive.)
9. Move the lens 5 cm closer to the object, and repeat. Stop when the image is further away than the end of the track.

Table 6. Real Image Data for a convex lens with expected focal length $f=$ $\qquad$

| Object Distance, <br> $p$ or $d_{o}(\mathrm{~cm})$ | Image Distance, <br> $q$ or $d_{i}(\mathrm{~cm})$ | $1 / d_{o}\left(\mathrm{~cm}^{-1}\right)$ | $1 / d_{i}\left(\mathrm{~cm}^{-1}\right)$ |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |

10. Calculate the inverses of the distances, and plot $1 / d_{i}$ vs. $1 / d_{o}$. Add a linear trendline and display the equation on the plot. The points should lie approximately along a line, with a slope of approximately -1 and an intercept of $1 / f$. Calculate the experimental focal distance from the intercept and compare it to the label on the lens, presenting them in a Table 6, commenting on the results in the figure caption.
Table 7. Results of Real Image Experiment. (Comment on results.)

| Intercept of Graph $(1 / \mathrm{cm})$ : |  |
| :--- | :--- |
| Experimental $f=1 /$ intercept $(\mathrm{cm}):$ |  |
| Focal Length $(\mathrm{cm})$ : |  |
| \% Difference |  |

Case 3: Virtual Images from Convex and Concave Lenses
11. Move the +250 mm lens closer to the lantern, to about the 20 cm mark. Look through the lens and observe the virtual image.
12. Replace the lens with the -150 mm concave lens. Compare the two virtual images. Record the image size as Reduced or Enlarged, and the Orientation as Upright or Inverted.
Table 8. Observations of Virtual Images.

| Lens Focal Length | Object Distance | Image Size | Orientation |
| :---: | :---: | :---: | :---: |
| +250 mm |  |  |  |
| -150 mm |  |  |  |

## Report Requirements

This lab report must be turned in on the day of the lab. An Abstract is not required. Simply turn in the Excel file. There should be clearly visible areas of the file with each Table and Figure, with captions written in the cells above or below them.

- 8 Tables with captions.
- 3 Figures of graphs, with trendlines and equations, with captions.
